Compact optical devices for computational imaging applications

Feng Tian is a Ph.D. graduate in Electrical and Computer Engineering at University of California, Davis. His research explores compact optical devices for computation imaging applications, a novel imager design strategy that uses custom design and fabricated optical phase mask to encode volumetric object information onto a 2D camera sensor, and physics-aware deep learning model to resolve 3D objects in real time. He also contributed to PSF engineering and optics design for multi-photon miniaturized endoscopes, which aims to perform in-vivo imaging by steering and focusing laser beams with a wearable device. He received the B.S. degree in electrical engineering from University of Electronic Science and Technology of China, and M.S. degree in electronics engineering and computer science from University of Michigan, Ann Arbor.

His research interests lie in machine learning methods for computational imaging and optical design strategies, physics-aware object reconstruction algorithms and inverse design of diffractive optical elements to solve challenges in miniaturized devices for neuroscience and machine vision studies.
